Data Availability Statements

Data are from the following sources.

- EU KLEMS Database (March 2008)
  - EU KLEMS data is available from the website http://www.euklems.net/. We have reproduced the raw data in the folder `data/raw/euklems`.
- UN National Accounts (2012)
  - UN National Accounts data is available with a permissible open license from http://data.un.org/. We have reproduced the raw data in the folder `data/raw/unna`.
- UNIDO INDTSTAT2
  - UNIDO Industrial Statistics Database can be purchased by anone for a fee. https://stat.unido.org/content/dataset_description/indstat-2-2018%252c-isic-revision-3
- Penn World Table 7.1
  - Penn World Table 7.1 can be used openly after proper attribution. We have reproduced the dataset with its citation in the folder `data/raw/pwt`.
- World Development Indicators (October 2015)
  - World Development Indicators is available at http://databank.worldbank.org/data/download/WDI_csv.zip under a CC-BY-4.0 license. We have not included the raw data in this replication package due to its size (267MB uncompressed).
- UN Comtrade (2015)
  - UN Comtrade is freely accessible online at https://comtrade.un.org/, with minimal technical limitations. (Queries are limited to 50,000 records each.) See usage terms at https://comtrade.un.org/db/help/PolicyOnUseAndRedissemination.pdf

Sample Definition

The core sample of countries include the United States, Mexico, Canada, Australia, China, Japan, South Korea, India, Colombia, the United Kingdom, a composite of France and its overseas departments, Germany, Italy, Spain, Portugal, a composite of Belgium and Luxembourg, the Netherlands, Finland, Sweden, Norway, Denmark, Greece, Austria and Ireland. Other countries are merged as "Rest of the World."

The data are disaggregated into 24 sectors: agriculture (including mining and quarrying), 22 manufacturing sectors, and services, all available in US dollars for the core countries and the Rest of the world (ROW). The 22 manufacturing sectors correspond to the industries numbered 15 to 37 in the ISIC Rev. 3 classification (36 and 37 are bundled together).

The final dataset is obtained by combining different sources and some estimation. The details are described in the Appendix of Caselli, Koren, Lisicky and Tenreyro (2019). The input data is stored, in comma delimited format, in the `data` folder.

Computational Requirements

Software Requirements

- Operating system: Max OS X or Linux.
- Julia (version 0.6.4)
  - JLD2 (version 0.0.6)
  - CSV (version 0.2.5)
  - DataFrames (version 0.11.7)
  - Plots (version 0.17.4)
  - Missings (version 0.2.10)
  - HypothesisTests (version 0.7.0)
  - Distributions (version 0.15.0)
  - Formatting (version 0.3.5)
  - Logging (version 0.3.1)

The necessary Julia packages are installed by `install.jl` or `make install`.

Memory and Runtime Requirements

Both Julia and Make can run in parallel. Computing the equilibrium for a given set of parameters takes about 1 minute on a single 3.8GHz CPU core. Each period's equilibrium can be computed in parallel (in Julia) and each scenario can be computed in parallel (in Make). With 44 scenarios (see below) and 36 time periods, total run time should be about 1600 minutes.

Instructions

The `Makefile` runs all the necessary computations in the correct order. If you want to reproduce the tables in our paper, run `make` or `make tables`. The Makefile is set to run 2 Julia threads in parallel (`PROCS = -p2`). If you have more cores, set `PROCS` accordingly. You can then run Make jobs in parallel with `make -j4 tables` .

To run the code in an AWS EC2 instance, follow the steps in `notebooks/aws-recipe.md` . You need to launch an instance from an EC2 image with Julia 0.6 preinstalled.

The core logic is in two files.

- `equilibrium.jl` calculates the equilibrium prices and quantities given a set of parameters.
- `calibrate_params.jl` calibrates parameters to match a set of data moments.

These modules are called by each scenario to be computed. An **experiment** is a set of common parameters applied to our economy *before calibration*. For example, `theta=4` is an experiment and so is `theta=8` . A **scenario** is a particular (often counterfactual) parametrization of an experiment. For example, given calibrated trade costs `kappa` , a scenario might reset those to their 1972 value.

As an example, consider the following two scenarios: `experiments/CES2/actual/scenario.jl` and `experiments/CES2/kappa1972/scenario.jl` . They belong to the same experiment, `experiments/CES2` , which calibrates its parameters *after* setting `sigma=2` in `experiments/CES2/init_parameters.jl` .

The `actual` scenario does not change any of the calibrated parameters. The `kappa1972` scenario replaces all `kappa` with the 1972 values in the same country and sector (see `experiments/CES2/kappa1972/change_parameters.jl`).

The results of each run are saved in `results.jld2` (a JLD2 Julia file format) in the *scenario* folder, such as `experiments/CES2/kappa1972/results.jld2` . Most of our tables require comparisons of four scenarios (with and without trade cost changes, with and without sectoral shocks). These tables are saved in the *experiment* folder, such as `experiments/CES2/output_table.csv` .

Algorithm

The calibration algorithm is described in Section III in the paper. The equilibrium solution algorithm is described in Section II.B. The basic outline of the equilibrium solution can be described by four nested loops.

- The **outer loop** solves for equilibrium labor shares, given expected wages. Expectations are taken over `S` possible realizations of future productivity shocks.
- The **adjustment loop** solves for equilibrium deviations from pre-decided labor shares, in response to shocks to productivity. This only runs when labor adjustment costs are finite, otherwise labor shares remain at their preassigned value.
- The **middle loop** solves for the equilibrium sectoral expenditure shares using resource constraints and market clearing conditions.
- The **inner loop** solves for the equilibrium intermediate goods prices across countries, given a *fixed* set of sectoral expenditure shares. The rest of the prices can be computed algebraically.

Data Structures

All parameters are stored in the dictionary `parameters` . Parameters can vary by m (destination country), n (source country), j (sector) and t (time). They are stored in a 4-dimensional array with indexes (m,n,j,t). If a certain dimension is not relevant for a parameter, that dimension is retained as a singleton dimension. This is to ensure that arrays are conforming to one another in size.

Similarly, all random variables computed in the equilibrium are stored as 4-dimensional arrays with m, n, j and s (state of the world) as indexes. This ensures conformability of variables and easy formulas such as

```
R_nt = sum(w_njt .* L_njt ./ beta_j, 3)
```

where the summation is across the third, j, dimension.

Output

Tables and figured are saved in the `output` folder.

File	Exhibit	Script
output/Figure2.pdf	Figure 2	notebooks/Create Figure 2.ipynb
output/table1.csv	Table 1	experiments/baseline
